(a) the displacement has a flip-specific direction
band: 95% bootstrap over events
flipped square, TPR direction: median +0.175
flipped square, linear-probe direction: median +0.163
unflipped discs (null): median -0.002
density over events (n = 1,596)
cos(Δ′, predicted flip direction at s)
Δ′ = act(P+m) − act(P+m′), flip-attributable
(b) and editing along it changes what the model plays
one point per edit scale (1-16); bars = 95% CI over events
TPR edit
linear-probe edit
random direction (null)
Δ log-mass onto the counterfactual legal set
↑ the model plays the un-flipped board
collateral: other squares whose decoded class changed (of 63)
